Lubricants compatible with elastomers and plastics
Lubricants compatible with elastomers and plastics

BECHEM – Lubrication solutions for industry

As the oldest German manufacturer of industrial lubricants, BECHEM is one of the leading producers of high-quality special lubricants and metalworking fluids today.

BECHEM products stand out through innovative formulations in the most diverse industrial applications – in machining and forming for metalworking processes, in coating technology and as for-life lubricants in various technical components.

A strong network of distributors and several national and international production sites ensure that BECHEM products are readily available worldwide.

Tomorrow’s technologies. Today.

All indications and values correspond to latest knowledge and do not represent any product specification.
The application of lubricants in contact with plastic materials is of growing importance. An essential requirement is the compatibility between lubricant and polymeric material. In the BECHEM laboratories a large variety of test equipment is available to check the compatibility of these materials. BECHEM products for plastic lubrication excel in outstanding compatibility with plastic and have proven their suitability worldwide in many applications under severest conditions.

In case of internal and/or external tensions at formed parts of thermoplastic and thermosetting polymers tension cracks may occur when getting in contact with lubricants.

Caused by wetting, diffusion and lubricant properties the following physical process can take place in case of incompatibility with the lubricant: Potential microscopically small cavities or tension cracks will lead to breakages due to the wetting and swelling ability of the lubricant. The physical condition of the highly polymeric formed construction part (morphology, molecular mass, molecular mass distribution, branching, cross-linking, internal stress and orientation) determines this process.

Polycarbonate, polystyrene, polymethylmethacrylate, styrene-acrylonitrile-copolymer and polyvinyl chloride without plasticizers are especially susceptible to tension cracking. Tension stress cracking behaviour can be determined by using standardised test specimen or the corresponding construction part itself. Tension crack formation can be partly or fully prevented by selecting the suitable lubricant.

Test specimen in bent strip test acc. to EN ISO 22088-3 without and with lubricant

Tensile strength test (upper picture) and hardness tests of elastomers

Physical interaction comprises two simultaneous processes:

A: Absorption of the lubricating medium by the sealing material
B: Extraction of the soluble parts – especially plasticizers – from the sealing material

The result is always a change in volume, i.e. swelling when A exceeds B or shrinking when B exceeds A. Each change in volume – whether swelling or shrinking – causes changes in the mechanical properties of the sealing material. This relates to hardness, elasticity, tensile strength and break elongation. Depending on the extent, these changes may lead to a complete destruction of the sealing material.

In case of chemical interaction the parts of the lubricating medium react with the sealing material which will change its structure, e.g. cross-linking or degradation. Slight chemical changes of the sealing material can lead to serious changes in the physical properties (embrittlement). The compatibility of elastomers with lubricants is examined according to defined test methods. In most cases changes in volume and hardness as well as tensile strength after a certain time of exposure under well defined conditions are analysed to determine compatibility.

### Abbreviation

**Elastomers**

- ACM: Acrylate rubber
- CR: Chloroprene rubber
- EPDM: Ethylene-propylene-diene rubber
- FKM/FPM: Fluorinated rubber
- FEPM: Fluoropropylene-tetrafluoroethylene rubber
- HNBR: Hydrogenated nitrile-butadiene rubber
- NBR: Nitrile-butadiene rubber
- SBR: Styrene-butadiene rubber

### Abbreviation

**Plastics (thermoplastics/thermosets)**

- ABS: Acrylonitrile-butadiene-styrene
- PA: Polyamide (polycaprolactam)
- PC: Polycarbonate
- PC/ABS: Polycarbonate-acrylonitrile-butadiene-styrene
- PE: Polyethylene
- PET/PBT: Polyethylene-terephthalate
- POM: Polyoxymethylene, polyacetal
- PP: Polypropylene
- PTFE: Polytetrafluoroethylene
- PU: Polyurethane
- PVC: Polyvinyl chloride
- TPE: Thermoplastic elastomer (polyether/polyester)

### The mentioned compatibilities are based on laboratory tests and references. In view of the variety of used raw materials as well as the complex chemical and morphological structure of the polymers the given information represent general tendencies only. In individual cases and especially prior to serial production the compatibilities should be confirmed by the supplier or verified in laboratory tests.
